SW	Surface Water

1Introduction

Our country is located in the Mediterranean basin, where the effects of global climate change are felt intensely, and is considered among the regions that will be most affected by the negative effects of climate change. Projections on how our water resources in our basins will be affected in the future due to climate change show that our water resources may decrease by up to 25 percent in the next hundred years.

For 2022, the annual amount of usable water per capita in our country is 1,313 m³, and it is expected that the annual amount of usable water per capita will fall below 1,000 cubic meters after 2030 due to human pressures and the effects of climate change. It is obvious that if the necessary measures are not taken, Turkey will become a country suffering from water scarcity in the very near future and will bring many negative social and economic consequences. As can be understood from the results of future projections, the risk of drought and water scarcity awaiting our country necessitates the efficient and sustainable use of our existing water resources.

The concept of water efficiency can be defined as "the use of the least amount of water in the production of a product or service". Water efficiency approach; It is based on the rational, sharing, equitable, efficient and effective use of water in all sectors, especially drinking water, agriculture, industry and household uses, taking into account the needs of not only people but also ecosystem sensitivity and all living things by protecting it in terms of quantity and quality.

With the increasing demand for water resources, the change in precipitation and temperature regimes as a result of climate change, the increase in population, urbanization and pollution, it is becoming more and more important to share the usable water resources among the users in a fair and balanced way. For this reason, it has become a necessity to create a roadmap based on efficiency and optimization in order to protect and use limited water resources with sustainable management practices.

In the sustainable development vision determined by the United Nations, Goal 7 from the Millennium Development Goals: Ensuring Environmental Sustainability and Goal 9 from the Sustainable Development Goals: Industry, Innovation and Infrastructure and Goal 12: Responsible Production and Consumption goals Issues such as efficient, fair and sustainable use of resources, especially water, environmentally friendly production and consumption that is the concern of future generations are included.

In the European Green Deal Action Plan prepared by our country within the scope of the European Green Deal, where member countries agree on goals such as implementing a clean, circular economy model with the goal of carbon neutrality, expanding the efficient use of resources and reducing environmental impacts, actions emphasizing water and resource efficiency in various fields, especially in industry, production and consumption have been determined.

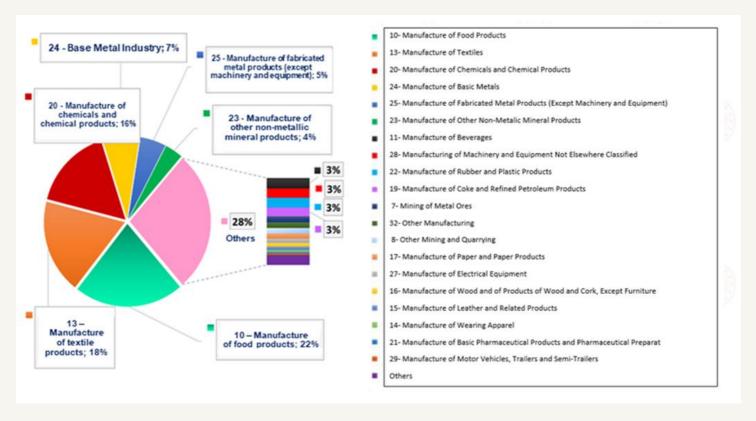

The "Industrial Emissions Directive (EED)", which is one of the most important components of the European Union environmental legislation in terms of industry, includes the measures to be taken to control, prevent or reduce the discharges/emissions from industrial activities to the receiving environment, including air, water and soil, with an integrated approach. In the Directive, Best Available Techniques (BATs) are presented in order to systematize the applicability of cleaner production processes and to eliminate the difficulties experienced in practice. Considering the costs and benefits, BATs are the most effective implementation techniques for a high level of environmental protection. In accordance with the Directive, Reference Documents (BAT-BREF) have been prepared for each sector, in which the BATs are explained in detail. In BREF documents, BATs are presented in a general framework such as good management practices, general water efficiency BATs, chemical use and management, techniques for various production processes, wastewater management, emission management and waste management.

The Ministry of Agriculture and Forestry, General Directorate of Water Management carries out studies aimed at disseminating efficient practices in urban, agricultural, industrial and individual water use and increasing social awareness. "Water Efficiency Strategy Document and Action Plan within the Framework of Adaptation to the Changing Climate (2023-2033)" entered into force with the Presidential Circular No. 2023/9Water efficiency action plans addressing all sectors and stakeholders have been prepared. In the Industrial Water Efficiency Action Plan, a total of 12 actions have been determined for the period 2023-2033 and responsible and relevant institutions have been appointed for these actions. Within the scope of the said Action Plan; Carrying out studies to determine specific water usage ranges and quality requirements on the basis of sub-sectors in the industry, organizing technical training programs and workshops on a sectoral basis, and preparing water efficiency guidance documents are defined as the responsibility of the General Directorate of Water Management.

On the other hand, with the "Industrial Water Use Efficiency Project According to NACE Codes" carried out by the Ministry of Agriculture and Forestry, General Directorate of Water Management, the best sectoral techniques specific to our country have been determined within the scope of studies to improve water efficiency in the industry. As a result of the study, sectoral guidance documents and action plans classified with NACE codes, which include the measures recommended to improve water use efficiency in sectors with high water consumption operating in our country, have been prepared.

As in the world, the sectors with the highest share in water consumption in our country are food, textile, chemistry and basic metal sectors. Within the scope of the studies, field visits were carried out in enterprises representing 152 sub-sectors in 35 main sectors, especially food, textile, chemistry, basic metal industry, which will represent production areas of different capacities and diversity within the scope of NACE Codes, which operate in our country and have high water consumption, and provide data on water supply, sectoral water use, wastewater generation and recycling. and the best available techniques (BAT) and sectoral reference documents (BREF) published by the European Union, water efficiency, cleaner production, water footprint, etc.

Distribution of water use in industry on a sectoral basis in our country

As a result of the studies, specific water consumption and potential savings rates for the processes of the enterprises were determined for 152 different 4-digit NACE codes with high water consumption, and water efficiency guidance documents were prepared by taking into account the EU best available techniques (BAT) and other cleaner production techniques. The guidelines include 500 techniques for water efficiency (BAT);

It has been examined under 4 main groups: (i) Good Management Practices, (ii) General Measures, (iii) Measures Related to Auxiliary Processes and (iv) Sector-Specific Measures.

Within the scope of the project, environmental benefits, operational data, technical specifications-requirements and applicability criteria were taken into account during the determination of BATs for each sector. In the determination of BATs, BREF documents were not limited to the BATs, but also different data sources such as current literature data, real case studies, innovative practices, and reports of sector representatives on a global scale were examined in detail and sectoral BAT lists were created. In order to evaluate the suitability of the BAT lists created for the local industrial infrastructure and capacity of our country, the BAT lists prepared specifically for each NACE code were prioritized by the enterprises by scoring them on the criteria of water saving, economic saving, environmental benefit, applicability, cross-media impact, and the final BAT lists were determined using the scoring results. Sectoral water efficiency guidelines have been created on the basis of the NACE code based on the water and wastewater data of the facilities visited within the scope of the project and the final BAT lists highlighted by the sectoral stakeholders and determined by taking into account the local dynamics specific to our country.

2 Scope of the Study

The guidance documents prepared within the scope of water efficiency measures in the industry include the following main sectors:

- Crop and animal production, hunting and related service activities (including sub-production areas represented by 6 four-digit NACE Codes)
- Fisheries and aquaculture (including 1 sub-production area represented by a four-digit NACE Code)
- Extraction of coal and lignite (including 2 sub-production areas represented by a four-digit NACE Code)
- Service activities in support of mining (including 1 sub-production area represented by a four-digit NACE Code)
- Metal ore mining (including 2 sub-production areas represented by a four-digit NACE Code)
- Other mining and quarrying (including 2 sub-production areas represented by a four-digit NACE Code)
- Manufacture of food products (including 22 sub-production areas represented by a four-digit NACE Code)
- Manufacture of beverages (including 4 sub-production areas represented by a four-digit NACE Code)
- Manufacture of tobacco products (including 1 sub-production area represented by a four-digit NACE Code)
- Manufacture of textiles (including 9 sub-production areas represented by a four-digit NACE Code)
- Manufacture of apparel (including 1 sub-production area represented by a four-digit NACE Code)
- Manufacture of leather and related products (including 3 sub-production areas represented by a four-digit NACE Code)
- Manufacture of wood, wood products and cork products (except furniture); manufacture of articles made by knitting from reeds, straw and similar materials (including 5 sub-production areas represented by a four-digit NACE Code)
- Manufacture of paper and paper products (including 3 sub-production areas represented by a four-digit NACE Code)
- Manufacture of coke and refined petroleum products (including 1 sub-production area represented by a four-digit NACE Code)
- Manufacture of chemicals and chemical products (including 13 sub-production areas represented by a four-digit NACE Code)
- Manufacture of basic pharmaceutical products and pharmaceutical materials (including 1 subproduction area represented by a four-digit NACE Code)
- Manufacture of rubber and plastic products (including 6 sub-production areas represented by a four-digit NACE Code)
- Manufacture of other non-metallic mineral products (including 12 sub-production areas represented by a four-digit NACE Code)
- Base metal industry (including 11 sub-production areas represented by a four-digit NACE Code)
- Manufacture of fabricated metal products (excluding machinery and equipment) (including 12 subproduction areas represented by a four-digit NACE Code)
- Manufacture of computers, electronic and optical products (including sub-production area represented by 2 four-digit NACE Codes)
- Manufacture of electrical equipment (including 7 sub-production areas represented by a four-digit NACE Code)
- Manufacture of machinery and equipment, n.e.c. (including 8 sub-production areas represented by a four-digit NACE Code)
- Manufacture of motor vehicles, trailers and semi-trailers (including 3 sub-production areas represented by a four-digit NACE Code)
- Manufacture of other means of transport (including 2 sub-production areas represented by a four-digit NACE Code)
- Other productions (including 2 sub-production areas represented by a four-digit NACE Code)
- Installation and repair of machinery and equipment (including 2 sub-production areas represented by a four-digit NACE Code)
- Electricity, gas, steam and ventilation system production and distribution (including 2 sub-production areas represented by a four-digit NACE Code)
- Waste collection, remediation and disposal activities; recovery of materials (including 1 subproduction area represented by a four-digit NACE Code)

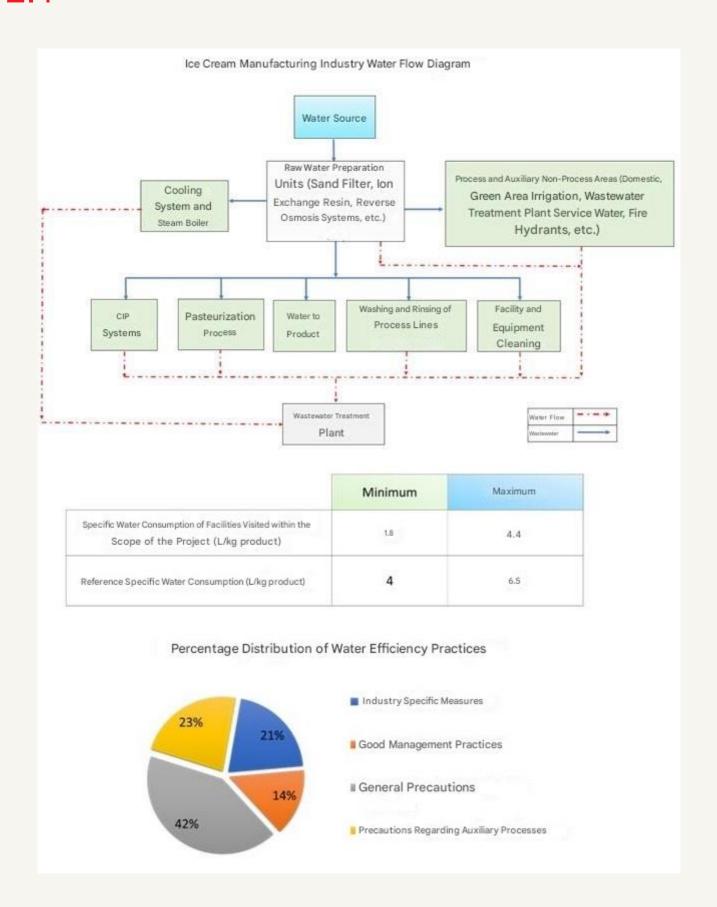

- Construction of non-building structures (including 1 sub-production area represented by a four-digit NACE Code)
- Storage and supporting activities for transportation (including 1 sub-production area represented by a four-digit NACE Code)
- Accommodation (including 1 sub-production area represented by a four-digit NACE Code)
- Educational Activities (Higher Education Campuses) (including 1 sub-production area represented by a four-digit NACE Code)
- Sports, entertainment and recreational activities (including 1 sub-production area represented by a four-digit NACE Code)

Manufacture of food products

The sub-production branches for which guide documents are prepared under the production of food products sector are as follows:

10.11	Processing and storage of meat
10.12	Processing and storage of poultry meat
10.13	Manufacture of products made from meat and poultry meat
10.20	Processing and storage of fish, shellfish and mollusks
10.31	Processing and storage of potatoes
10.32	Manufacture of vegetable and fruit juice
10.39	Processing and storage of fruits and vegetables n.e.c.
10.41	Manufacture of oils and fats
10.42	Manufacture of margarine and similar edible fats
10.51	Dairy management and cheese manufacturing
10.52	Ice cream manufacturing
10.61	Manufacture of milled cereals and vegetable products
10.62	Manufacture of starch and starchy products
10.71	Manufacture of bread, fresh patisserie products and fresh cakes
10.72	Manufacture of rusks and biscuits; Durable patisserie products and durable cake manufacturing
10.73	Manufacture of pasta, noodles, couscous and similar bakery products
10.81	Manufacture of sugar
10.82	Manufacture of cocoa, chocolate and confectionery
10.83	Processing of coffee and tea
10.84	Manufacture of spices, sauces, vinegars and other condiments
10.85	Manufacture of ready meals
10.89	Manufacture of other foodstuffs n.e.c.

2.1 Ice Cream Manufacturing (NACE 10.52)

In the production of ice cream, cream and thickening materials are homogenized in the blender. The mixture is delivered to the pasteurization vat through pipes. It is purified from microorganisms by the pasteurization process. It is subjected to the forging process to get a consistency. Here, the milk cream particles are broken down and made inseparable from the milk. After mixing with colorants and flavors such as vanilla or strawberry, it is left to cool. As the mixture passes through a continuous cooler, air is sprayed into it. Fruit, nuts, peanuts or other small pieces are added to the ice cream. Finally, the ice creams are packaged and frozen in a passage with air-blowing propellers.

As there are water added to the product content in the sector, water consumption is realized in the pasteurization unit, cleaning of process lines and sanitation processes. In the ice cream production sector, a significant amount of water is consumed, especially in Clean In Place (CIP) and Clean Out of Place (COP) systems. There is a need for demineralized water for the water added to the product in the sector. Soft water is required for use in other areas of production. In raw water preparation units such as activated carbon filters, ion exchange resins, reverse osmosis used in soft water production, significant water consumption is also realized for filter washing, resin regeneration and membrane cleaning processes. In addition, water is consumed in auxiliary units such as cooling towers and steam boilers.

The reference specific water consumption in the ice cream manufacturing sector is in the range of 4-6.5 L/kg (Valta et al., 2014). The specific water consumption of the production branch analyzed within the scope of the study is in the range of 1.8-4.4 L/kg. With the implementation of sector-specific techniques, good management practices, measures in the nature of general measures and measures related to auxiliary processes, in the sector It is possible to achieve 39-73% water recovery.

10.52 Ice Cream Manufacturing The priority water efficiency implementation techniques recommended under the NACE code are presented in the table below.

NACE Code	NACE Code Description		Industry-First Available Best Techniques
10.52			Industry-Specific Measures
	ı ıring	1.	Reuse of wastewater from activated sludge treatment in a clean-in- place (CIP) process
	rean facti	2.	Installation of strainers and/or traps in transmission channels
	Ice Cream Manufacturing	3.	Computer-controlled milk transfer, pasteurization, homogenization and use of CIP equipment
		4.	Providing water recovery from steam from evaporator plants
		5.	Separation of process outputs to optimize use, reuse, recovery, recycling and disposal
		6.	Using dry cleaning methods
		7.	Reducing the frequency of cleaning of centrifugal separators by improving pre-milk filtration
		8.	The use of in-line storage tanks in pasteurizers
		9.	The use of heated water in the cooling process for product cleaning
		10.	Use of cooling tower blowdown water for plant and equipment cleaning
			Good Management Practices
		1.	Using an integrated wastewater management and treatment strategy to reduce the amount of wastewater and the pollutant load
		2.	Establishment of an environmental management system
		3.	Preparation of water flow diagrams and mass balances for water
		4.	Preparation of a water efficiency action plan to reduce water use and prevent water pollution
		5.	Providing technical training to personnel for the reduction and optimization of water use
		6.	Good production planning to optimize water consumption
		7.	Setting water efficiency targets
		8.	Monitoring the amount and quality of the water used in production processes and auxiliary processes and the wastewater generated and adapting this information to the environmental management system

NACE Code	NACE Code Description		Industry-First Available Best Techniques
10.52			General Water Efficiency BATs
	Ð	1.	Minimization of spills and leaks
	Ice Cream Manufacturing	2.	Recovery of water from rinsing solutions and reuse of recovered water in processes appropriate to its quality
		3.	Use of automatic equipment and equipment (sensors, smart hand washing systems, etc.) that will save water at water usage points such as showers/toilets, etc.
		4.	Use of pressure washers for equipment cleaning, general cleaning, etc.
		5.	Reuse of filter wash water in filtration processes, reuse of relatively clean cleaning water in production processes, and reduction of water consumption by using clean-in-place systems (CIP)
		6.	Avoiding the use of drinking water in production lines
		7.	Use of cooling water as process water in other processes
		8.	Detection and reduction of water losses
		9.	Use of automatic check-off valves to optimise water use
		10.	Documentation of production procedures and use by employees to prevent waste of water and energy
		11.	Reuse of pressurized filtration backwash water prior to water softening at appropriate points
		12.	Optimising the frequency and duration of regeneration (including rinses) in water softening systems
		13.	Construction of closed storage and impermeable waste/scrap yard to prevent the transportation of toxic or hazardous chemicals for the aquatic environment
		14.	Storage, storage and prevention of substances that pose a risk in the aquatic environment (such as oils, emulsions, binders) and mixing with wastewater after use
		15.	Prevention of mixing of clean water streams with dirty water streams
		16.	Characterizing the amount and quality of wastewater at all wastewater formation points and determining the wastewater flows that can be reused with or without treatment
		17.	Use of closed-loop water cycles in appropriate processes
		18.	Computer-aided control systems in production processes Use

NACE Code	NACE Code Description		Sectorally prioritized BATs
10.52	ıalatı	19.	Untreated reuse of relatively clean wastewater from washing, rinsing and equipment cleaning in production processes Separate collection
	Dondurma İmalatı	20.	and treatment of grey water in the plant and high water quality In areas that do not require (green area irrigation, floor, floor washing, etc Use
		21.	Implementation of time optimization in production and arrangement of all processes to be completed as soon as possible
		22.	Avoiding the need for rinsing between activities by using compatible chemicals in successive processes
			Precautions for Auxiliary Processes
		1.	To the principle of reverse osmosis of old equipment in the ventilation system with ion exchange resins (systems that produce demineralized water) replacement and reuse of water
		2.	Reuse of the liquid formed by condensation from the ventilation system Avoiding unnecessary cooling processes by identifying processes that need
		-4.	wet cooling
			Reduction of water consumption in closed-loop cooling systems by increasing the number of cycles and improving the quality of the catch-up water
		5.	Reduction of evaporation losses in closed-loop cooling water Water
			recovery with tower cooling application in non-closed-loop systems
		6. 7.	Increasing the number of cycles by using anti-corrosion and anti-scale inhibitors in systems with a closed water loop
		8.	Use of air-cooling systems instead of water cooling in cooling
		0.	systems
		-9. -10.	Installation of water softening systems for the healthy operation of cooling water recovery systems
			Use of a closed-loop refrigeration system to reduce water use
		11.	In some periods of the year, when the need for cooling is low, cooling with local dry air
		12.	Collecting the water generated by surface runoff with a separate collection system and using it for cooling water, process water, etc.
A total c	of 52 techn	ique	es have been proposed in this sector.

ve been proposed in this sector.

Ice Cream Manufacturing NACE Code;

- (i) Sector-Specific Measures,
- (ii) Good Management Practices,
- (iii) General Water Efficiency BATs and
- (iv) Measures related to auxiliary processes are given under separate headings.

2.1.1 Sector-Specific Measures

Dairy management and cheese production, ice cream manufacturing

Separation of process outputs to optimize use, reuse, recovery, recycling and disposal

Process outputs can be separated manually or mechanically using equipment such as splash guards, flaps, catch containers, drip trays and chutes. Efficient collection of materials reduces the volume of water required for cleaning. Cross-contamination between different by-products can also be reduced if sufficient quantities of separate collection systems are provided. Examples of separating process outputs in the dairy industry are as follows:

- Collection of whey that is not involved in the production of cheese or other products,
- Collection of milky wastewater formed at the beginning of pasteurizers,
- Taking back milk by presses from products rejected due to defective production,
- Preventing the mixing of solid wastes obtained after centrifugation with wastewater,
- Separation and collection of buttermilk, first clear part and residual oil in butter churning processes and using it as a base for low-fat spreads,
- Collection of incorrectly filled products for use for animal feed, etc.,
- Measuring the turbidity values of the fats/solids in the line and directing them to the balance tank for reuse in the pasteurizer to increase product yield.

Using dry cleaning methods

Removing solid residues from the system using compressed air, vacuum, or catch containers with mesh lids reduces the amount of material entrained into the wastewater and thus COD and BOD emission levels. The recovery potential of the substances produced in the process increases. Since dry cleaning methods will be used, water consumption is reduced.

Examples of applications related to this technique are:

- Adoption of dry cleaning methods for the collection of solid residues,
- Sweeping solid residues instead of washing,
- Evaluating the spilled products as solid waste instead of transferring them to the wastewater channel.
- Installation of strainers to prevent solids from entering wastewater.

• Installation of strainers and/or traps in transmission channels

Installing strainers in the transmission channels to prevent any solids from entering the wastewater ensures that the amount of matter entrained in the wastewater is reduced and therefore the COD and BOD pollution load.

Reuse of wastewater from activated sludge treatment in a clean-in-place (CIP) process

Water reuse can be achieved by using membrane filtration techniques in dairies. Used water from various dairy production steps can be recovered by membrane filtration techniques (IPPC BREF, 2019). Recovered high-quality water; boiler feed water can be reused as process, cooling and/or rinsing water (IPPC BREF, 2019). With this technique, water savings of up to 50% can be achieved. In addition, valuable by-products can be obtained and waste generation can be reduced (IPPC BREF, 2019).

Providing water recovery from steam from evaporator plants

Condensates from steam plants can be converted into water by filtering in a condensate polisher using reverse osmosis. Condensate rinse aids are used to filter water condensed from steam (IPPC BREF, 2019). With this application, water savings of up to 50% can be achieved.

Reducing the frequency of cleaning of centrifugal separators by improving pre-milk filtration

By improving pre-milk filtration and clarification processes, deposits in centrifugal separators are minimized, resulting in a reduction in the need for centrifugal cleaning and thus a reduction in the frequency of cleaning. Thus, a reduction in water consumption and wastewater pollution is achieved (IPPC BREF, 2019).

The use of heated water in the cooling process for product cleaning

Water reuse possibilities in dairy farming applications are possible as long as they meet hygiene and food safety requirements. One of these alternatives is the reuse of cooling water as cleaning water.

Use of cooling tower blowdown water for plant and equipment cleaning

Water savings can be achieved if the amount of blowdown is reduced or if blowdown water is reused without treatment in areas that do not require high water quality (TOB, 2021). In addition, in some industrial facilities, it may be possible to treat the cooling system blowdown water and reuse it as process water (TOB, 2021).

Computer-controlled milk transfer, pasteurization, homogenization and use of CIP equipment

The use of computer-controlled milk transfer, pasteurization, homogenization and CIP equipment in dairies is an important measure to save water and energy as well as reduce wastewater pollution.

In the computer-controlled system, milk intake is carried out by means of two parallel programmable logic-controlled closed systems. The use of special valves can significantly reduce milk losses (IPPC BREF, 2019). Where valves are activated, milk losses due to personnel errors during interpipe transfer and during filling of tanks and wastewater pollution resulting from this can be reduced. With automatic dosing, approximately 15% savings are achieved both in water and in the consumption of cleaning and disinfecting agents. In addition, milk is pasteurized by computer-controlled plate heat exchangers, which have a larger surface area than others for heat exchange and are equipped with automatic fat standardization and homogenization units. The process is carried out in a closed system. The control of the storage of raw materials, intermediates and products, as well as their pumping into the different processing units of the plant, is carried out by a computer-aided system. The same control system drives the CIP system. Here, the final rinse water is used for the next cleaning cycle (IPPC BREF, 2019).

Ice Cream Production Process

• The use of in-line storage tanks in pasteurizers

The capacity of each component can be designed to be optimized relative to the others in order to prevent product build-up or product shortages in the lines due to differences in the speeds of the processes in the production line and synchronization mismatch. For example, if the capacity of in-line storage tanks is too low compared to the output of the pasteurizer on a pasteurization line, the milk needs to be recirculated in the pasteurizer several times throughout the day. This consumes energy and damages the quality of the product, as well as increases the frequency of cleaning of the pasteurizer. By adapting the size/number of inline storage tanks to the output of the pasteurizer and optimizing product changeovers, line interruptions and circulation of milk in the pasteurizer can be avoided or reduced. Reducing the frequency of cleaning reduces the consumption of energy, water and chemicals, as well as the negative impact of excessive heat treatment on product quality (IPPC BREF, 2019).

2.12 Good Management Practices

• Establishment of an environmental management system

Environmental Management Systems (EMS) include the organizational structure, responsibilities, procedures and resources required to develop, implement and monitor the environmental policies of industrial organizations. The establishment of the environmental management system improves the decision-making processes of institutions between raw materials, water-wastewater infrastructure, planned production process, and different treatment techniques. Environmental management organizes how to manage resource procurement and waste discharge demands with the highest economic efficiency, without compromising product quality and with the least possible impact on the environment.

The most widely used Environmental Management Standard is ISO 14001. Alternatives include the Eco Management and Audit Programme Directive (EMAS) (761/2001). It has been developed for the evaluation, improvement and reporting of the environmental performance of enterprises. It is one of the leading practices within the scope of ecoefficiency (cleaner production) in EU legislation and participation is provided voluntarily (TUBITAK MAM, 2016; TOB, 2021). The benefits of establishing and implementing an Environmental Management System are as follows:

- Economic benefits can be achieved by improving business performance (Christopher, 1998).
- International Organization for Standardization (ISO) standards are adopted, resulting in greater compliance with global legal and regulatory requirements (Christopher, 1998).
- While the penalty risks related to environmental responsibilities are minimized, the amount of waste, resource consumption and operating costs are reduced (Delmas, 2009).
- The use of internationally accepted environmental standards eliminates the need for multiple registrations and certifications for businesses operating in different locations around the world (Hutchens Jr., 2017).
- Especially in recent years, the improvement of the internal control processes of companies is also important to consumers. The implementation of environmental management systems provides a competitive advantage over companies that do not adopt the standard. It also contributes to the better position of institutions in international areas/markets (Potoski & Prakash, 2005).

The benefits listed above depend on numerous factors such as the production process, management practices, resource use, and potential environmental impacts (TOB, 2021). Savings of 3-5% in water consumption can be achieved with applications such as the preparation of annual inventory reports with similar content to the environmental management system and monitoring of inputs and outputs in production processes in terms of quantity and quality (Öztürk, 2014). The total duration of the EMS development and implementation phases is estimated to be 8-12 months (ISO 14001 User Manual, 2015).

Industrial organizations also carry out studies within the scope of the ISO 14046 Water Footprint Standard, which is an international standard that defines the requirements and guidelines for assessing and reporting their water footprint. With the implementation of the relevant standard, it is aimed to reduce the use of fresh water and environmental impacts required for production. In addition, the ISO 46001 Water Efficiency Management Systems Standard, which helps industrial organizations to save water and reduce operating costs, helps organizations to improve their water efficiency policies by monitoring, benchmarking and reviewing.

• Using an integrated wastewater management and treatment strategy to reduce the amount of wastewater and the pollutant load

Wastewater management should be based on a holistic approach from wastewater production to final disposal and includes functional elements such as composition, collection, treatment including sludge disposal and reuse. The selection of appropriate treatment technology for industrial wastewater depends on integrated factors such as land availability, desired treated water quality, and compliance with national and local regulations (Abbassi & Al Baz, 2008).

The reuse of treated wastewater at the plant not only improves the quality of water bodies, but also reduces the demand for fresh water. Therefore, it is very important to determine the appropriate treatment strategies for different reuse targets.

In integrated industrial wastewater treatment, different aspects such as wastewater collection system, treatment process, and reuse target are evaluated together (Naghedi et al., 2020). For industrial wastewater recovery, an integrated wastewater management framework can be determined by combining methods such as SWOT method (strengths, weaknesses, opportunities and threats), PESTEL method (political, economic, social, technological, environmental and legal factors), decision tree with expert opinions (Naghedi et al., 2020). Integrating the Analytical Hierarchy Process (AHP) and Unified Consensus Solution (CoCoSo) techniques can be used to set priorities for industrial wastewater management processes based on a multitude of criteria (Adar et al., 2021).

With the implementation of integrated wastewater management strategies, an average reduction of up to 25% in water consumption, wastewater quantity and pollution loads of wastewater can be achieved. The potential payback period of the application ranges from 1-10 years (MoAF, 2021).

Industrial Wastewater Treatment Plant

• Providing technical training to personnel for the reduction and optimization of water use

With this measure, water saving and water recovery can be achieved by increasing the training and awareness of the personnel, and water efficiency can be achieved by reducing water consumption and costs. Due to the fact that the personnel do not have the necessary technical knowledge in industrial facilities, problems may arise with the use of high amounts of water and wastewater formation. For example, it is important that cooling tower operators, who represent a significant proportion of water consumption in industrial operations, are properly trained and have technical knowledge. In applications such as determining water quality requirements in production processes, measuring water and wastewater amounts, etc., it is necessary for the relevant personnel to have sufficient technical knowledge (MoAF, 2021). For this reason, it is important to provide training to staff on water use reduction, optimization and water saving policies. Practices such as involving personnel in water conservation studies, creating regular reports on water usage amounts before and after water efficiency initiatives, and sharing these reports with personnel support participation and motivation in the process. The technical, economic and environmental benefits to be obtained through personnel training give results in the medium or long term (TUBITAK MAM, 2016; MoAF, 2021).

• Good production planning to optimize water consumption

In industrial production processes, planning a raw material until it turns into a product by using the least process is an effective practice to reduce labor costs, resource use costs and environmental impacts and to ensure efficiency (TUBITAK MAM, 2016; MoAF, 2021). Production planning in industrial facilities by considering the water efficiency factor reduces water consumption and wastewater. Modifying production processes or combining some processes in industrial facilities provides significant benefits in terms of water efficiency and time planning (MoAF, 2021).

• Preparation of a water efficiency action plan in order to reduce water use and prevent water pollution Preparation of an action plan that includes what to do in the short, medium and long term in order to reduce the amount of water-wastewater in industrial facilities and to prevent water pollution in terms of water efficiency

Important. At this point, determining the water needs throughout the facility and in the production processes, water

quality requirements should be determined at the points of use, wastewater formation points and wastewater characterization should be done (MoAF, 2021). At the same time, it is necessary to determine the measures to be implemented to reduce water consumption, wastewater generation and pollution loads, to make feasibility and to prepare action plans for the short-medium-long term. In this way, water efficiency and sustainable water use are ensured in facilities (MoAF, 2021).

Setting water efficiency targets

The first step in achieving water efficiency in industrial facilities is to set targets (MoAF, 2021). For this, first of all, a detailed water efficiency analysis should be carried out on the basis of processes. Thus, unnecessary water use, water losses, wrong practices affecting water efficiency, process losses, reusable water-wastewater resources with or without treatment can be determined. It is also extremely important to set water saving potential and water efficiency targets for each production process and the plant as a whole (MoAF, 2021).

• Preparation of water flow diagrams and mass balances for water

Determination of water use and wastewater generation points in industrial facilities, creation of water-wastewater balances in production processes and auxiliary processes other than production processes are the basis of many good management practices in general. Creation of process profiles throughout the plant and on the basis of production processes; It facilitates the identification of unnecessary water usage points and high water use points, the evaluation of water recovery opportunities, process modifications and the determination of water losses (MoAF, 2021).

 Monitoring the water used in production processes and auxiliary processes and the wastewater generated in terms of quantity and quality and adapting this information to the environmental management system, There are resource uses in industrial facilities, and as a result of resource use,

Inefficiency and environmental problems can be caused by input-output flows. Therefore It is necessary to monitor the water and wastewater used in production processes and auxiliary processes in terms of their quantity and quality (TUBITAK MAM, 2016; MoAF, 2021). Processbased quantity and quality monitoring, together with other good management practices (personnel training, establishment of an environmental management system, etc.), can be used to reduce energy consumption by 6-10%, water consumption and wastewater amounts. It can provide a reduction of up to 25% (Öztürk, 2014).

The main stages for monitoring water and wastewater in terms of quantity and quality are:

- Use of monitoring equipment (such as meters) to monitor consumption of water, energy, etc. on the basis of processes,
- Establishment of monitoring procedures,
- Determining the use/exit points of all inputs and outputs (raw materials, chemicals, water, products, wastewater, sludge, solid waste, hazardous waste and by-products) related to the production process, monitoring, documenting, comparatively evaluating and reporting in terms of their quantity and quality,
- Monitoring raw material losses in production processes where raw materials are transformed into products and taking measures against raw material losses (MoEUB, 2020e).

2.1.3 General Water Efficiency BATs

Detection and reduction of water losses

In industrial production processes, water losses occur in equipment, pumps and pipelines. First of all, water losses should be detected and leaks should be prevented by keeping equipment, pumps and pipelines in good condition by performing regular maintenance (IPPC BREF, 2003). Regular maintenance procedures should be established and particular attention should be paid to the following:

- Adding pumps, valves, level switches, pressure and flow regulators to the maintenance checklist,
- Carrying out inspections not only in the water system, but also especially for heat transfer and chemical distribution systems, broken and leaking pipes, barrels, pumps and valves,
- regular cleaning of filters and pipelines,
- Calibrating, routinely checking and monitoring measuring equipment such as chemical measuring and dispensing instruments, thermometers, etc. (IPPC BREF, 2003).

With effective maintenance-repair, cleaning and loss control practices, savings ranging from 1-6% in water consumption can be achieved (Öztürk, 2014).

Minimization of spills and leaks

Both raw material and water losses can be experienced due to spills and leaks in enterprises. In addition, if wet cleaning methods are used to clean the spilled areas, there may be increases in water consumption, wastewater amounts and pollution loads of wastewater (MoAF, 2021). In order to reduce raw material and product losses, spillage and splash losses are reduced by using anti-splashes, fins, drip trays, sieves (IPPC BREF, 2019).

• Untreated reuse of relatively clean wastewater from washing, rinsing and equipment cleaning in production processes

In industrial facilities, relatively clean wastewater, especially washing-final rinsing wastewater and filter backwash wastewater, can be recycled without treatment in floor washing and garden irrigation processes that do not require high water quality, saving between 1-5% in raw water consumption. The initial investment costs required for the application consist of the establishment of new pipelines and reserved tanks (Öztürk, 2014).

Prevention of mixing of clean water streams with dirty water streams

By determining the wastewater formation points and characterizing the wastewater in industrial facilities, wastewater with high pollution load and relatively clean wastewater can be collected in separate lines (TUBITAK MAM, 2016; MoAF, 2021). In this way, wastewater streams of appropriate quality can be reused with or without treatment. By separating wastewater streams, water pollution is reduced, treatment performances are increased, energy consumption can be reduced in relation to reducing treatment needs, and emissions are reduced by ensuring wastewater recovery and recovery of valuable materials. In addition, heat recovery from separated hot wastewater streams is also possible (TUBITAK MAM, 2016; MoAF, 2021) Separation of wastewater streams often require high investment costs, and costs can be reduced when it is possible to recover large amounts of wastewater and energy (IPPC BREF, 2006).

• Characterizing the amount and quality of wastewater at all wastewater formation points and determining the wastewater flows that can be reused with or without treatment

By determining and characterizing wastewater formation points in industrial facilities, it is possible to reuse various wastewater streams with or without treatment (Öztürk, 2014; TUBITAK MAM, 2016; MoAF, 2021). In this context, filter backwash water, RO concentrates, blowdown water, condensate water, relatively clean washing and rinsing water can be reused without treatment in the same/different processes and in areas that do not require high water quality (such as plant and equipment cleaning). Apart from this, it is possible to reuse wastewater streams that cannot be reused directly in production processes after they are treated using appropriate treatment technologies.

Membrane filtration processes are an integral part of many wastewater reuse systems. Nanofiltration (NF) and Reverse osmosis (RO) filtration systems are used for industrial wastewater recovery. Microfiltration (MF) and ultrafiltration (UF) are often used for the pretreatment of water before it goes to the NF or RO process (Singh et al., 2014).

In some industrial facilities operating in the food sector, water consumption can be reduced by 13%, wastewater amounts by 18% and COD loads of wastewater by up to 48% by recycling wastewater with or without treatment (TUBITAK MAM, 2016; MoAF, 2021). In addition, the payback period required for the application was calculated as approximately 3 years (energy savings were also taken into account) (TUBITAK MAM, 2016; MoAF, 2021).

• Use of cooling water as process water in other processes

Water cooling systems are widely used in processes where thermal energy is used intensively and cooling is required. It is possible to save water and energy by using heat exchangers in cooling water return, preventing contamination of cooling water and increasing cooling water return rates (TUBITAK MAM, 2016; MoAF, 2021). In addition, if the cooling water is collected separately, it is often possible to use the collected water for cooling purposes or to reuse it in appropriate processes (EC, 2009). With the reuse of cooling water, 2-9% of total water consumption can be saved (Greer et al., 2013). Savings of up to 10% can be achieved in energy consumption (Öztürk, 2014; MoAF, 2021).

• Use of pressure washers for equipment cleaning, general cleaning, etc.

Water nozzles are widely used in equipment plant cleaning. Effective results can be obtained by using correctly placed, appropriate nozzles to reduce water consumption and wastewater pollution loads. The use of active sensors and nozzles where high water consumption occurs and where possible is very important for the efficient use of water. Thanks to the replacement of mechanical equipment with pressurized nozzles, it is possible to achieve significant water savings (TUBITAK MAM, 2016). Reducing water consumption, wastewater generation and wastewater pollution load through the use of water pressure-optimised nozzles in technically feasible processes are the main environmental benefits of the application.

Use of automatic check-off valves to optimise water use

Monitoring and controlling water consumption using flow control devices, meters and computer-aided monitoring systems provides significant technical, environmental and economic advantages (Öztürk, 2014). Monitoring the amount of water consumed within the facility and in various processes prevents water losses (TUBITAK MAM, 2016). It is necessary to use flow meters and meters in the facility and production processes, to use automatic shut-off valves and valves in continuously operating machines, to develop monitoring-control mechanisms according to water consumption and some determined quality parameters using computer-aided systems (TUBITAK MAM, 2016). With this application, it is possible to save up to 20-30% in water consumption on a process basis (DEPA, 2002; LCPC, 2010; IPPC BREF, 2003). By monitoring and controlling water consumption on a process basis, 3-5% savings can be achieved in process water consumption (Öztürk, 2014).

Avoiding the use of drinking water in production lines

In different sub-sectors of the manufacturing industry, water with different water quality can be used in accordance with production purposes. In industrial facilities, raw water obtained from underground water sources is used in production processes after being treated. However, in some cases, although it is costly in production processes, drinking water can be used directly or raw water is disinfected with chlorinated compounds and evaluated in production processes. These waters, which contain residual chlorine, can react with organic compounds (natural organic substances (DOM)) in the water in the production processes and form disinfectant by-products harmful to living metabolisms (Özdemir & Toröz, 2010; Oğur et al.; MoAF, 2021). The use of drinking water containing residual chlorine compounds or raw water disinfected with chlorinated compounds should be avoided as much as possible. In the disinfection of raw water, disinfection methods with high oxidation ability such as ultraviolet (UV), ultrasound (US) or ozone can be used instead of chlorine disinfection. In order to increase the technical, economic and environmental benefits to be provided by the application, determining and using the water quality parameters required in each production process helps to reduce unnecessary water supply and treatment costs. With this application, it is possible to reduce water, energy and chemical costs (TUBITAK MAM, 2016).

• Recovery of water from rinsing solutions and reuse of recovered water in processes appropriate to its quality

Rinsing wastewater in industrial facilities can be reused without treatment in relatively clean wastewater, floor washing and garden irrigation processes that do not require high water quality (Öztürk, 2014). In raw water consumption with the recovery of rinse water Savings of 1-5% can be achieved.

• Avoiding the need for rinsing between activities by using compatible chemicals in successive processes

Chemical compatibility is a measure of how stable a substance is when mixed with another substance. If two substances mix with each other and undergo a chemical reaction, they are considered incompatible.

Various chemicals are used in industrial facilities to increase washing and rinsing efficiency. The fact that these chemicals are compatible and act as solvents shows a positive course in increasing efficiency. Therefore, dirt on the material can be removed in a shorter time and more effectively, and the amount of water used in washing processes can be significantly reduced. In this case, even if the amount of wastewater can be reduced, there may be an increase in the chemical loads carried by the wastewater. These negative effects can be minimized by ensuring that the washing water containing solvents used in the washing and rinsing processes is reused.

It is possible to save 25-50% of water by reusing washing water. Reserved tanks and new pipelines may be needed for the application. In alternative cases, the washing solution is kept directly in the system and can be used many times until it loses its properties.

Optimising the frequency and duration of regeneration (including rinses) in water softening systems

Cationic ion exchange resins, which are one of the most commonly used methods for softening raw water in industrial facilities, are routinely regenerated. In regeneration, pre-washing, brine regeneration and final rinsing processes are carried out using raw water, respectively. Regeneration periods are determined depending on the hardness of the water. If the hardness is high, more frequent regeneration should be done in water softening systems.

In regeneration processes, washing, regeneration and rinsing wastewater are usually removed directly. However, if the washing and final rinsing water is of raw water quality, it can be sent to the raw water tank or reused in processes that do not require high water quality, such as facility cleaning and green area irrigation (MoAF, 2021).

It is very important to determine the optimum regeneration frequency in regeneration systems. Although regeneration in water softening systems is adjusted according to the frequency recommended by the supplier or depending on the flow rate and time entering the softening system, this frequency also varies depending on the calcium concentration in the raw water. For this reason, online hardness measurement is applied when determining the frequency of regeneration. Thus, regeneration frequencies can be optimized, as well as excessive washing, rinsing or backwashing with salt water can be prevented by using online hardness sensors.

• Reuse of pressurized filtration backwash water prior to water softening at appropriate points

Softened waters with low calcium and magnesium concentrations are needed for many industrial processes. With water softening systems, calcium, magnesium and some other metal cations in hard water are removed from the water and soft water is obtained.

Savings are achieved by reusing pressurized filtration backwash water at appropriate points before water softening. This measure is similar in content to applications such as "Reuse of filter backwash water in filtration processes, relatively cleaning water in production processes, and reducing water consumption by using in-situ cleaning systems".

• Use of closed-loop water cycles in appropriate processes

In general, refrigerants are chemical compounds with certain thermodynamic properties that affect the performance of the cooling process, taking heat from the substances to be cooled and cooling them (Kuprasertwong et al., 2021).

Water is used as a refrigerant in manufacturing industry processes and in many processes led by product cooling. While this cooling process is carried out, the water can be reused through the cooling tower or central cooling systems. If unwanted microbial growth occurs in the cooling water, it can be controlled by adding chemicals to the recirculation water (TUBITAK MAM, 2016).

By reusing cooling water in processes such as cleaning, water consumption and the amount of wastewater generated are reduced. However, the need for energy for cooling and recirculation of cooling water emerges as a side interaction.

Heat recovery is also provided by the use of heat exchangers in cooling waters. Generally, closed loop systems are used in facilities where water cooling systems are used. However, the cooling system blowdowns are removed by giving them directly into the wastewater treatment plant channel. These removed blowdown waters can be reused in suitable production processes.

• Storage, storage and prevention of substances that pose a risk in the aquatic environment (such as oils, emulsions, binders) and mixing with wastewater after use

In industrial facilities, dry cleaning techniques can be used to prevent chemicals that pose a risk to the aquatic environment, such as oils, emulsions and binders, from mixing with wastewater streams and leaks can be prevented. In this way, the protection of water resources can be ensured (TUBITAK MAM, 2016).

• Construction of closed storage and impermeable waste/scrap yard to prevent the transportation of toxic or hazardous chemicals for the aquatic environment

In industrial facilities, closed and impermeable waste/scrap storage areas can be built to prevent the transport of toxic or dangerous chemicals to the receiving environments for the aquatic environment. This practice is already being implemented within the scope of the current environmental regulations in our country. Within the scope of the field studies carried out, a separate collection channel can be built in the toxic or hazardous substance storage areas in industrial facilities to prevent the separate collection of the leachate in question and its mixing with the natural water environments.

• Separate collection and treatment of gray water in the facility and use it in areas that do not require high water quality (green area irrigation, floor, floor washing, etc.)

Wastewater generated in industrial facilities is not only industrial wastewater originating from production processes, but also includes wastewater originating from showers, sinks, kitchens, etc. Wastewater consisting of showers, sinks, kitchens, etc. is called gray water. Water savings can be achieved by treating these gray waters with various treatment processes and using them in areas that do not require high water quality.

Use of computer-aided control systems in production processes

Since inefficient resource use and environmental problems in industrial facilities are directly related to input-output flows, process inputs-outputs should be defined in the best way specific to production processes (TUBITAK MAM, 2016). Thus, it becomes possible to develop measures to increase resource efficiency, economic and environmental performance. Organizing input-output inventories is considered a prerequisite for continuous improvement. While such management practices require the participation of technical staff and senior management, they pay for themselves in a short time with the work of various experts (IPPC BREF, 2003). It is necessary to use measurement equipment on the basis of application processes and to perform some routine analyzes/measurements specific to the processes. In order to obtain the highest level of efficiency from the application, using computerized monitoring systems as much as possible ensures that the technical, economic and environmental benefits to be obtained are increased (TUBITAK MAM, 2016).

• Use of automatic equipment and equipment (sensors, smart hand washing systems, etc.) that will save water at water usage points such as showers/toilets, etc.

Water is very important in many sectors of the manufacturing industry, both for production processes and for personnel to provide the necessary hygiene standards. Water consumption can be achieved in various ways in the production processes of industrial facilities, as well as savings in water consumption by using equipment such as sensor taps and smart hand washing systems in the water usage areas of the personnel. Smart hand washing systems adjust the water, soap and air mixture in the right proportion and provide resource efficiency in addition to water savings.

 Reuse of filter wash water in filtration processes, reuse of relatively clean cleaning water in production processes, and reduction of water consumption by using clean-in-place systems (CIP)

Wastewater from backwashes of activated carbon filters and softening devices often contains only a high percentage of suspended solids (AKM). Backwash water, which is one of the easiest wastewater types to recycle, can be recovered by filtering with ultrafiltration plants. In this way, water savings of up to 15% are achieved (URL - 1, 2021).

Regeneration wastewater formed after the regeneration process is soft water with high salt content and constitutes approximately 5-10% of total water consumption. It is ensured that regeneration wastewater is collected in a separate tank and evaluated in processes with high salt requirements, facility cleaning and domestic use. For this, a reserved tank, plumbing and pump are needed. With the reuse of regeneration wastewater, water consumption, energy consumption, wastewater amounts and salt content of wastewater are reduced by approximately 5-10% (Öztürk, 2014). The payback period varies according to the consumption of regeneration water in production processes, facility cleaning and domestic use. It is estimated that if regeneration water is reused in production processes that require high salt (since both water and salt will be recovered), the potential payback period will be less than one year. It is estimated that the payback period will be over one year for facility and equipment cleaning and domestic uses (MoAF, 2021).

In our country, reverse osmosis (RO) concentrates are combined with other wastewater streams and given to the wastewater treatment plant channel. The concentrates formed in the RO systems used for additional hardness removal can be used in garden irrigation, inplant and tank-equipment cleaning (TUBITAK MAM, 2016; MoAF, 2021). In addition, with the structuring of raw water quality monitoring, it is possible to re-evaluate RO concentrates by feeding them back into raw water reservoirs and mixing them (MoAF, 2021).

• Implementation of time optimization in production and arrangement of all processes to be completed as soon as possible

In industrial production processes, planning the process from raw material to product transformation using the least process is an effective practice to reduce labor costs, resource use costs and environmental impacts and to ensure efficiency. In this context, it may be necessary to review the production processes and revise them to use the least number of process steps (TUBITAK MAM, 2016). In cases where the desired product quality cannot be achieved due to some inadequacies, inefficiency and design errors in basic production processes, production processes may need to be renewed. Therefore, in this case, the use of resources required in the manufacture of the unit amount of product and the amount of waste, emissions and solid waste generated increase. Time optimization in production processes is an effective practice (TUBITAK MAM, 2016).

Documentation of production procedures and use by employees to prevent waste of water and energy

In order to make efficient production in an enterprise, effective procedures should be applied in order to identify and evaluate potential problems and their sources and to control the production stages (Ayan, 2010). Determining and implementing appropriate procedures in production processes ensures more efficient use of resources (such as raw materials, water, energy, chemicals, personnel and time) and assurance of reliability and quality in production processes (Ayan, 2010). The presence of documented production procedures in production processes contributes to the development of the ability to develop sudden reflexes for the evaluation of operational performance and the solution of problems (TUBITAK MAM, 2016; MoAF, 2021). Effective implementation and monitoring of procedures created specifically for production processes is one of the most effective ways to ensure product quality, to receive feedback and to develop solution proposals (Ayan, 2010). Documenting, effectively implementing and monitoring production procedures is a good management practice and is an effective tool in structuring and ensuring the continuity of the cleaner production approach and environmental management system. In addition to the potential benefits, there may be changes in the cost and economic gains of the application depending on the sector or facility structure (TUBITAK MAM, 2016; MoAF, 2021). Although the establishment and monitoring of production procedures is not costly, the payback period may be short considering the savings and benefits it will provide (TUBITAK MAM, 2016; MoAF, 2021).

2.1.4Precautions for Auxiliary Processes

BATs for refrigeration systems

• Reduction of water consumption in closed-loop cooling systems by increasing the number of cycles and improving the quality of the catch-up water

Water is used as a refrigerant in many processes such as the production processes of the manufacturing industry and the cooling of products. Water is recirculated through a cooling tower or central cooling systems and the cooling process is carried out. If an undesirable microbial growth occurs in the cooling water, it can be controlled by adding chemicals to the recirculation water (TUBITAK MAM, 2016). In the recirculation process, the number of cycles can be increased by good chemical conditioning. In this way, water can be saved by reducing the amount of fresh water fed into the system. In addition, good conditioning of the cooling completion water can also increase the number of cycles (MoAF, 2021).

• In some periods of the year, when the need for cooling is low, cooling with local dry air

In cases where the need for cooling is low, it is possible to save water by cooling with dry air.

- The use of air cooling systems instead of water cooling in cooling systems Industrial cooling systems are used to cool heated products, processes and equipment. For this purpose, closed and open circuit cooling systems can be used, as well as a industrial refrigeration systems using fluid (gas or liquid) or dry air (IPPC BREF, 2001b; MoAF, 2021). Air cooling systems consist of finned tube elements, condensers and air fans (IPPC BREF, 2001b; MoAF, 2021). Air cooling systems can have different operating principles. In industrial air-cooling systems, heated water is air-cooled in closed-loop refrigerant condensers and heat exchangers (IPPC BREF, 2001b; MoAF, 2021). In water cooling systems, the heated water is taken to a cooling tower and the water is cooled in drip systems. However, although water-cooled systems operate in a closed circuit, a significant amount of evaporation occurs. In addition, since some water is blown down in cooling systems, water is lost in this way (IPPC BREF, 2001b; MoAF, 2021). The use of air-cooling systems instead of water in cooling systems is effective in reducing evaporation losses and also reducing the risk of contamination of cooling water (IPPC BREF, 2001b; MoAF, 2021).
- Water recovery with tower cooling application in systems that do not have a closed loop
 Cooling towers are divided into two as counter-flow and cross-flow according to their
 working principles. In counter-flow cooling towers, the airflow is upward, diagonally
 In flow-through cooling towers, on the other hand, the air flow moves horizontally as the water
 flows downward.

The water, which is exposed to fresh air, cools down until it descends into the cold-water pool, where it is collected and sent to the facility. During these processes, some of the water evaporates. The air, whose humidity increases as a result of the evaporation of water, is thrown into the atmosphere from the fan chimney at the top of the tower. Evaporation losses in cooling towers must be managed effectively.

Various chemicals are used in cooling towers to prevent the formation of bacteria and parasites and to control lime residues. These chemicals condense with the evaporation of water and cause unwanted sediment and deposits within the tower. A blowdown system is used to keep this concentration at a certain level. Blowdown water can be recovered by treatment with the use of membrane filtration systems or ion exchange resins. Recycling of blowdown wastewater is important in terms of water efficiency.

• Avoiding unnecessary cooling processes by identifying processes that need wet cooling: The boundaries of the plant site affect design parameters such as cooling tower height. Hybrid cooling system in cases where it is necessary to reduce the tower height can be applied. Hybrid refrigeration systems with and without evaporation (wet and dry) is a combination of cooling systems. Depending on the ambient temperature, the hybrid cooling tower can be operated as a completely wet cooling tower or as a combined wet/dry cooling tower (TUBITAK MAM, 2016). In regions where there is not enough cooling water or in cases where water costs are high, the evaluation of dry cooling systems or hybrid cooling systems can be an effective solution to reduce the amount of cooling supplement water (TUBITAK MAM, 2016).

• Increasing the number of cycles by using anti-corrosion and anti-scale inhibitors in systems with a closed water loop

Cooling towers and evaporative condensers are efficient and cost-effective systems that remove heat from air conditioning and industrial process cooling systems (IPPC BREF, 2001b; MoAF, 2021). More than 95% of the circulating water in these systems can be recovered (TUBITAK MAM, 2016). In cooling systems, impurities remain in the recirculation water due to the fact that some of the recirculation water is worked on the basis of evaporation, and the impurity concentrations gradually increase in each cycle. Impurities that can be included in the cooling system together with the air can cause contamination in the recirculation water (TUBITAK MAM, 2016). If impurities and contaminants are not effectively controlled, they can cause the formation of boilerstone and corrosion, unwanted biological growth and sludge accumulation. This can become a chronic problem that leads to a decrease in the efficiency of heat transfer surfaces and an increase in operating costs. In this case, it is necessary to implement a water treatment program specially designed in terms of the quality of the feed water supplied to the cooling system, the cooling water system building material and operating conditions. In this context; blowdown control, biological growth control, corrosion control, avoiding the use of hard water, using sludge control chemicals, using filtration and sieve systems may be appropriate (TUBITAK MAM, 2016). In addition, the establishment and periodic implementation of an effective cleaning procedure and program is a good management practice in terms of protecting cooling systems. Corrosion is one of the most important problems in cooling systems. In the tower recirculation water, as the degree of hardness increases, dissolved solids (sulfate, chloride, carbonate, etc.) that cause corrosion as a result of the formation of limestone and deposits on the walls will cause abrasion on the surface over time. In addition, the formation of deposits negatively affects heat transfer and reduces energy efficiency. In order to prevent these negativities, it is necessary to implement a lime and corrosion preventive chemical conditioning program, to disinfect with biocide that prevents biological activation, to clean the sediments by subjecting the cooling towers in use to chemical and mechanical cleaning at least twice a year, and to keep the hardness and conductivity values of the reinforcement water as low as possible (IPPC BREF, 2001; Kayabek et al., 2005). In order to improve the quality of the supplementary water, it may be necessary to treat (condition) it using an appropriate treatment system. In addition, unwanted microbial growth needs to be kept under control (IPPC BREF, 2001b; MoAF, 2021). Due to micro-residues and deposits in the cooling water, blowdown occurs in cooling systems as well as in steam boilers. Deliberate draining of the cooling system to bring the increased density of solids in the cooling system to balance is called cooling blowdown. It is possible to reduce the use of biocides and blowdown amounts by pre-treating cooling water with appropriate methods and continuous monitoring of cooling water quality (TUBITAK MAM, 2016). Although the investment cost depends on the scale of the application, the payback period in expected investment expenses varies between 3 and 4 years (IPPC BREF, 2001).

• Collecting the water generated by surface runoff with a separate collection system and using it for cooling water, process water, etc.

In most industrial facilities, wastewater is generated from process-sourced or non-process-based areas. The resulting wastewater can be treated and reused in appropriate places. By reusing the wastewater generated in the facility after treatment, savings can be achieved at varying rates in various industrial facilities. Water generated by surface runoff can be collected with a separate collection system and used as cooling water (MoAF, 2021).

• Reduction of evaporation losses in closed-loop cooling water

Some water evaporates during the cooling of the heated water in the cooling systems. Therefore, in closed-loop cooling systems, cooling water is added as much as the amount of evaporated water. Evaporation losses can be avoided by optimizing cooling systems. In addition, a reduction in the amount of blowdown can be achieved with applications such as the treatment of completion water added to cooling systems and the prevention of biological growth in cooling systems. Within the scope of the field studies carried out, the blowdown water formed in the cooling system is generally removed by giving it directly to the wastewater channel. By reusing the cooling system blowdown water, up to 50% of the water consumption of the cooling systems can be saved. To implement this measure, it may be necessary to install new pipelines and reserved tanks. (MoAF, 2021).

• Use of a closed-loop refrigeration system to reduce water use

Some water evaporates during the cooling of the heated water in the cooling systems. Therefore, in closed-loop cooling systems, cooling water is added as much as the amount of evaporated water. Evaporation losses can be avoided by optimizing cooling systems. In addition, applications such as purification of completion water added to cooling systems and prevention of biological growth in cooling systems can also reduce the amount of blowdowns. Within the scope of the field studies carried out, the blowdown water generated in the cooling system is not used back and is removed by giving it directly to the wastewater channel. Water consumption in cooling systems by reusing cooling system blowdown water

Savings of up to 50% can be achieved. The initial investment costs required for this application may include the installation of new pipelines and reserved tanks. In this case, it can be predicted that the required initial investment cost will vary between 5,000-20,000 TL (MoAF, 2021).

 Installation of water softening systems for the healthy operation of cooling water recovery systems

Cooling water is collected separately and used for cooling purposes or reused in appropriate processes (EC, 2009). In order for this system to work properly, a water softening system is required. It has suitable water quality in terms of cooling water, cleaning and reuse as irrigation water. However, due to the fact that it contains some hardness in its use as cooling water, an additional softening is required in order to prevent corrosion problems that will occur over time. Cooling water or before it can be reused in the process, these waters must be properly disinfected. In addition, it is possible to reuse the water in question not only in cooling processes but also in all production processes by treating it with appropriate treatment techniques (membrane filtration, advanced oxidation, chemical precipitation, granular activated carbon adsorption, etc.) (TUBITAK MAM, 2016). As the hardness of the cooling water increases, limestone and debris formation occurs on the walls. Deposit formation negatively affects heat transfer, reducing energy efficiency and increasing energy costs. With the increase in evaporation in the system, the ion concentration and conductivity value in the water increases. In order to prevent these negativities, it is necessary to apply lime and anti-corrosion chemical conditioning to the cooling water, to disinfect with a biocide that prevents biological activation, to subject the cooling towers to chemical and mechanical cleaning at least twice a year, to clean the sediments, and to keep the hardness and conductivity values as low as possible (TUBITAK MAM, 2016).

BATs for ventilation and air conditioning systems

- Reuse of the liquid formed by condensation from the ventilation system During the ventilation cycle, condensate with good water quality can be produced in the system. For example, in a facility in Spain, the conductivity of about 200 µS in the ventilation system It has condensate water collected in a tank and flushed the automatic galvanizing line (MedClean, n.d.).
- Replacement of old equipment in the aeration system with ion exchange resins based on the principle of reverse osmosis (systems that produce demineralized water) and reuse of water Conductivity of the final effluent using ion exchange resins in the aeration system. It is brought to a conductivity level suitable for use for equipment cleaning. Example In a facility in Spain, effluent with a conductivity value of approximately 1000 µS is obtained by replacing the equipment in the ventilation system with ion exchange resins and reused in the system (MedClean, n.d.).
